Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).

## Description

The present invention provides a stabilized growth hormone, a method for its preparation and a process for effecting growth promotion in an animal by administering an effective amount of stabilized growth promoting hormone. The stabilizers decrease the formation of insolubles and preserve the soluble bioactivity of the growth promoting hormone in aqueous environments. One major problem in the administration of growth promoting hormones is the denaturation of the native globular structure causing aggregation of the growth hormone into precipitated forms which decreases the amount of active growth hormone available. The formation of these insolubles can also block tubing, membranes and various pumps of the implanted delivery devices. System failure almost always results due to the formation of these insolubles. In addition to the formation of insolubles, another problem in the administration of growth promoting hormones is retaining the soluble bioactivity of the hormone. Therefore, to properly serve as a stabilizer for growth promoting formulations, the stabilizer must decrease the formation of insolubles and maintain the bioactivity of the soluble growth hormone.

A variety of stabilizers have been disclosed in the art which avoid the breakdown of the structures of proteins. For example, glycerol has been used to stabilize the activity of various proteins. Gekko, et al., *Biochemistry* (1981), 20, pp. 4666-76. Examples of proteins which are described in this article include chymotrypsinogen A (from bovine pancreas), ribonuclease A (from bovine pancreas),  $\beta$ -lactoglobulin (from milk), bovine serum albumin, insulin (bovine pancreatic), egg-white lysozyme and  $\alpha$ -chymotrypsin.

U.S. Patent No. 4,179,337 discloses a process for coupling a polypeptide such as enzymes and insulin to polyethylene glycol or polypropylene glycol having a molecular weight of 500 to 20,000 daltons. The polyethylene glycol or polypropylene glycol is described as protecting the polypeptide from loss of activity and the composition can be injected without any immunogenic response.

U.S. Patent No. 4,439,181 discloses a method for preventing the precipitation of proteins within drug delivery systems that depend on the fluidity of the infusate for proper function. The method comprises mixing a polyol with the protein solution prior to introduction of the solution into the drug delivery system. Examples of the polyols which are described include glycerol and biocompatible C-4 to C-18 polyols. Exemplary of the polyols are erythritol, arabinose, xylose, ribose, adonitol, arabitol, rhamose, inositol, fructose, galactose, glucose, mannose, sorbose, maltose, sucrose, melezitose, and raffinose. The solid polyols are dissolved in a standard aqueous solution and admixed with the insulin to provide the final concentration of polyol in the solution of about 10 to 30 percent weight per volume, with the balance being the protein. Other proteins which are described as being subject to the same precipitation problems include growth hormone, glucagon and the like.

EP-A-0193917 describes growth hormone preparations containing large water-soluble carbohydrate polymers which act to delay release of the growth hormone from the preparation. The compositions may also contain a variety of additional constituents, including for example sorbitol, but no mention is made of the potential uses of sorbitol, in the absence of a large carbohydrate polymer, in conjunction with growth hormones and further does not disclose the stabilising effect of sorbitol on the growth hormone.

While the prior art has taught a number of various stabilizers for specific proteins, unfortunately, the fact a particular stabilizer is effective with a particular protein does not necessarily mean that the particular stabilizer is appropriate for the stabilization of a growth promoting hormone. Therefore, there exists a need for a method of stabilization of a growth promoting hormone which decreases the formation of insolubles and preserves the soluble bioactivity of the hormone.

The present invention concerns a stabilized animal growth promoting hormone and a method for its manufacture. This invention provides for the decreased formation of insolubles and preservation of the soluble bioactivity of the growth promoting hormone in an aqueous environment. The stabilized growth hormone can be formed by mixing a growth promoting hormone with an effective amount of a stabilizer selected from one or more of the following:

- (a) a polyol selected from non-reducing sugars, sugar alcohols, sugar acids, pentaerythritol and lactose, with the proviso that where the polyol is a sugar alcohol, the formulation does not contain carbohydrate polymer(s);
- (b) an amino acid selected from glycine, sarcosine, lysine or salts thereof, serine, arginine or salts thereof, betaine, N,N-dimethyl-glycine, aspartic acid or salts thereof, glutamic acid or salts thereof;
- (c) a polymer of an amino acid having a charged side group at a physiological pH selected from polylysine, polyaspartic acid, polyarginine, polyhistidine, polyornithine and salts thereof;
- (d) a choline derivative selected from choline chloride, choline dihydrogen citrate, choline bitartrate, choline bicarbonate, tricholine citrate, choline ascorbate, choline borate, choline gluconate, choline phosphate, di(choline)sulfate and dicholine mucate.

Fig. 1 is a graph showing the mean number of ng of porcine growth hormone per ml of blood serum corresponding to the time at which the blood serum sample was taken after implantation.

The present invention is directed to a stabilized animal growth promoting hormone, a method for its preparation and a process for effecting growth promotion in an animal by administering an effective amount of the stabilized growth promoting hormone. The stabilizers of the present invention not only decrease the formation of insolubles but preserve the bioactivity of the soluble portion of the growth hormone. According to the present invention, an effective amount of a stabilizer is mixed with a growth promoting hormone prior to administration of the hormone to the animal. In one embodiment of the present invention, the stabilized growth promoting hormones are injected into the animal. In this embodiment, the stabilized growth hormones are in an aqueous solution comprising dissolved growth hormone and dissolved stabilizer. According to another embodiment of the present invention, the stabilized growth promoting hormones are administered via an implant device. According to this embodiment, the stabilized growth hormones can be in a liquid or dry state. Preferably, when an implant device is elected for the method of administration, the stabilized growth hormone is in the form of a dry mixture comprising solid growth hormone and solid stabilizer which, upon implantation in an aqueous environment, gets wetted and starts to dissolve.

The stabilizers are particularly suited for animal growth promoting hormones. Examples of such hormones include bovine, human, equine, avian, ovine and porcine growth promoting hormones. Preferably, the hormone is bovine or porcine growth promoting hormone. While the concentration of the growth promoting hormone may vary depending on the desired dosage and the particular growth promoting hormone, the hormone is generally present in amounts of from 1 to 97.5 percent by weight of the total weight of the growth promoting formulation. Preferably, the growth promoting hormone is present in amounts of from 5 to 50 percent of the overall weight of the growth promoting formulation. As one skilled in the art can appreciate, the growth hormones may comprise a high weight percent of the overall weight of the growth promoting formulation when the formulation is in the solid state since water and other suitable aqueous solvents are not needed to enable the formulation to be injectable.

The growth hormones for use in the present invention can be derived by extraction and subsequent concentration techniques from the pituitary glands of various animals. Growth hormones which are produced by recombinant DNA methods are also suitable. The amino acid sequences of various hormones which are suitable in the present invention are known. For example, the amino acid sequence of human growth promoting hormones is described in an article by C.H. Li in Kirk-Othmer "Encyclopedia of Chemical Technology", 3rd E., Vol. 12, pp. 549-552. The amino acid sequence of bovine growth hormone is described in an article by R.P. Woychik, *Nucleic Acid Res.*, 10, 7197 (1982). The amino acid sequence of ovine growth hormone is described in an article by C.H. Liu et al., *Arch. Biochem. Biophys.*, 156, 493-508 (1973). The amino acid sequence of porcine growth hormone is described in an article by P.H. Seeburg et al., *DNA*, 2, 37, 45 (1983). In addition to the above, one can also use growth hormones that have been modified by excision of up to 12 amino acid residues from the amino ends of the amino acid sequences.

The stabilizers which are suitable for the present invention generally have two characteristics. First, they are generally very polar. Second, the stabilizers must be soluble in aqueous solutions. According to one embodiment, the stabilizer is preferably present in amounts sufficient such that when the stabilizer-growth hormone formulation is in an aqueous environment or solution, the solution is saturated with the stabilizer. Obviously, the various stabilizers have their own respective solubilities and may be present in different amounts. When the growth promoting formulation is dispersed or dissolved in an aqueous solution, the stabilizer should be from about 5 percent by weight up to total saturation in the aqueous formulation containing the growth hormone. When the dry formulation is elected, the stabilizer may comprise higher weight percentages of the overall formulation since a major constituent, i.e. the water or aqueous solvent is eliminated. Accordingly, the respective weight percentages of the specific stabilizers listed below are inclusive of both aqueous formulations as well as solid formulations containing the stabilizer and growth promoting hormone.

Stabilizers which can be used in the present invention are polyols selected from non-reducing sugars, sugar alcohols, sugar acids, lactose and pentaerythritol. One example of a non-reducing sugar is sucrose. Examples of sugar alcohols include mannitol, xylitol, erythritol, threitol, sorbitol and glycerol. An example of a sugar acid is L-gluconate and the metallic salts thereof. Preferably, the polyol is xylitol. Contrary to what one would believe after reading many of the prior art references and especially U.S. Patent No. 4,439,181, not all polyols are appropriate for stabilizing growth promoting hormones. Whilst many polyols may provide for the decrease in the formation of insolubles, some do not preserve the bioactivity of the soluble portion of the growth promoting hormone. Examples of such polyols include the reducing sugars for example, fructose, mannose, and maltose. Lactose, which is a reducing sugar, seems to be an exception to the remaining reducing sugars. As one skilled in the art will appreciate, the polyols which are used in the

present invention have a variety of solubilities in water. While the amount of polyol is present in stabilizing amounts, the polyol can be present in amounts of from 2.5 to 99 percent by weight of the total weight of the overall formulation prior to introduction into an aqueous environment. Preferably, the polyol is present in amounts of from 15 to 60 percent by weight.

5 Other stabilizers which are suitable for the present invention are certain amino acids. Examples of amino acids which can be used include glycine, sarcosine, lysine or salts thereof, serine, arginine or salts thereof, betaine, N,N-dimethylglycine, aspartic acid or salts thereof, glutamic acid or salts thereof. Mixtures of such amino acids can also be used. Preferably, the amino acid is sarcosine. While the amino acid is present in stabilizing amounts, they are generally present in amounts of from 2.5 to 99 percent by weight of the total weight of the overall formulation prior to introduction into an aqueous environment. Preferably, the amino acid is present in amounts of from 15 to 60 percent by weight.

Certain polymers of amino acids have been found to be useful stabilizers for growth hormones. These polyamino acids or salts thereof can be characterized by charged side groups at physiological pH. The charge can be either "+" or "-". Some examples of polyamino acids which provide a stabilizing effect include polylysine, polyaspartic acid, polyarginine, polyhistidine, polyornithine and salts of such polyamino acids. Preferably, the polyamino acid salt is poly DL-lysine HBr. Generally, these particular stabilizers are present in amounts of from 2.5 to 99 percent by weight of the total weight of the overall formulation. Preferably, the polyamino acid derivative is present in amounts of from 15 to 60 percent by weight.

Another class of stabilizers which can be used are derivatives of choline. Examples of such stabilizers include choline chloride, choline dihydrogen citrate, choline bitartrate, choline bicarbonate, tricholine citrate, choline ascorbate, choline borate, choline gluconate, choline phosphate, di(choline) sulfate and dicholine mucate. Preferably, the choline derivative is choline chloride. Generally, these stabilizers are present in amounts of from 2.5 to 99 percent by weight of the total weight of the overall formulation prior to introduction into an aqueous environment. Preferably, the choline derivative is present in amounts of from 15 to 60 percent by weight of the total weight of the overall formulation.

The preparation of the stabilized growth promoting formulations containing the stabilizer and the growth hormone may be by simple mechanical mixing. When an injectable form of the stabilized growth promoting formulation is desired, the stabilizer is first dispersed in an aqueous solution which can be stirred or shaken to bring about a more rapid solubilization of the stabilizer. After the aqueous solution of the stabilizer has been formed, the growth promoting hormone is added. The weight percentage of the aqueous solvent or water need only be an amount sufficient to dissolve the stabilizer and growth hormone and to allow the formulation to be administered by injection. Amounts ranging from 40 to 90 percent by weight are believed to be suitable. While the above procedure has been described as being the preferred, the order of addition can be altered. In another embodiment, the stabilizer and growth hormone can be wet or dry mixed to provide a solid formulation which is particularly suited for implants. After the growth hormone and the stabilizer have been mixed, any other optional additives, such as buffers, salts and adjuvants, may be added.

Since the present growth hormone formulations are intended to be administered to an animal, the pH must be physiologically acceptable to the animal and not contribute to the destabilization of the growth promoting hormone. Generally, the pH of the stabilized growth promoting formulation ranges from 4 to 10, with the preferred pH range being from 6.5 to 8.0. The pH of the growth promoting formulation can be adjusted by effective amounts of a pharmaceutically acceptable base or acid to obtain the required pH. Suitable acids and bases are known to those skilled in the art.

This invention additionally provides a method for effecting growth promotion in animals which comprises administering to the animal an effective amount of a stabilized growth promoting formulation comprising a growth promoting amount of a growth promoting hormone with a stabilizing amount of a stabilizer selected from one or more of the following:

- (a) a polyol selected from non-reducing sugars, sugar alcohols, sugar acids, lactose, and pentaerythritol, with the proviso that where the polyol is a sugar alcohol, the formulation does not contain carbohydrate polymer(s);
- (b) an amino acid selected from glycine, sarcosine, lysine or salts thereof, serine, arginine or salts thereof, betaine, N,N-dimethylglycine, aspartic acid or salts thereof, glutamic acid or salts thereof;
- (c) a polymer of an amino acid having charged side groups at physiological pH selected from polylysine, polyaspartic acid, polyarginine, polyhistidine, polyornithine and salts thereof;
- (d) a choline derivative selected from choline chloride, choline dihydrogen citrate, choline bitartrate, choline bicarbonate, tricholine citrate, choline ascorbate, choline borate, choline gluconate, choline phosphate, di(choline)sulfate and dicholine mucate.

The growth promoting formulations are for administration to an animal and preferably pigs and cows.

These formulations can be administered in a variety of ways. In one embodiment, the growth promoting formulation can be in a liquid form of solution which is administered by subcutaneous injection or via a liquid containing reservoir of an implanted delivery device.

In another embodiment, the stabilized growth hormone formulation is compressed into tablet or pellet form prior to being placed in a reservoir of a delivery device. In order to formulate pellets from the stabilized growth promoting formulation, various binders are preferably used. Examples of binders which are suitable include sodium bentonite, ethyl cellulose, stearic acid, calcium stearate, adipic acid, fumaric acid, polyethylene glycol, deacetylated chiton and cellulose acetate. Generally, the binder is present in amounts of from .5 to 10 percent by weight of the total weight of the solid growth promoting formulation. Preferably, the binder is present in amounts of from 1 to 5 percent by weight.

Lubricants are preferably added to the pellet to assist in the achievement of a sustained release pattern of the pellet and to assist in the ease of manufacture. Examples of such lubricants includes those common tablet water insoluble lubricants such as, for example, magnesium stearate, sodium stearate, calcium stearate, powdered stearate acid, talc, paraffin, cocoa butter, graphite, lycopodium or combinations thereof. Preferably, the lubricant is a fatty acid derivative such as the stearates, including magnesium stearate, sodium stearate, and calcium stearate. While the amount of lubricant may vary, the lubricant is generally present in amounts of from 0.5 to 10 percent by weight of the total weight of the pellet. Preferably, the lubricant is present in amounts of from 1 to 5 percent by weight.

The stabilized growth hormone formulation, preferably pelletized, may be placed within the reservoir of a delivery device. The reservoir is defined and surrounded by a wall, at least a portion of which comprises a porous membrane. The materials suitable for forming the porous part of the external wall of the device are generally those through which the stabilizer and growth hormone can pass via pores. The pore size of the porous materials can be from 5  $\mu\text{m}$  to 250  $\mu\text{m}$ , with 10 to 100  $\mu\text{m}$  being preferred. Suitable materials for forming these walls are naturally occurring or synthetic materials that are biologically compatible with body fluids, tissues and organs and essentially insoluble in body fluids with which the device will come into contact. The use of materials soluble in body fluids is undesirable, since dissolution of the wall of the device would affect both the rate of release of the growth hormone and the capability of the system to remain in place for prolonged periods of time. The material also desirably is characterized by constant porosity; if the porosity changes over time the rate of release of the growth hormone also will change over time.

Materials suitable for forming the porous portion of the wall of the device are known in the art as having a plurality of fused particles which provide a supporting structure having microscopic sized interconnecting pores. A variety of such materials are commercially available or can be made by different methods known in the art, including etched nuclear track, leaching, polyelectrolytic processes, ion exchange polymer reactions and other techniques. See, for example, Synthetic Polymer Membranes, R.E. Kesting, Chapters 4 and 5, published by McGraw-Hill, 1971; and Chemical Reviews: Ultrafiltration 18: 363-455 (1934).

Microporous materials useful for making these parts of the devices of the present invention include microporous polyalkylenes, such as microporous polyethylene, microporous polycarbonates, microporous polyamides, microporous modacrylic copolymers, polyesters prepared by esterification of a dicarboxylic acid or anhydride with an alkylene polyol, phenolic polyesters, cross-linked olefin polymers, polyolefins, polyurethanes, polyimides, and polybenzimidazoles. Preferred microporous materials are microporous polyethylene.

As one skilled in the art can appreciate, the rate of diffusion of the contents of the reservoir will depend upon the particular material, the ingredients of the reservoir, pore size of the porous material and the dimensions of the porous materials, i.e. thickness and surface area. While the present invention is not limited to any particular dimensions of the porous portion of the device, excellent results have been achieved with microporous polyethylene discs having a pore size of from 10 to 70  $\mu\text{m}$ , a diameter of 2 to 4 mm and thickness of 1.5 to 3 mm.

In the devices which can be advantageously used in connection with the present invention, typically only a portion of the external wall comprises a porous material. The remainder of the wall comprises a material that is essentially impermeable to the growth hormone and stabilizer(s) contained in the reservoir and to body fluids which are in contact with the implanted or inserted device. This portion of the external wall desirably is characterized much as the porous part of the wall was characterized above. The material should be compatible with body fluids, tissues and organs, and can comprise materials which are commercially available or can be made by processes known in the art. Suitable impermeable materials include steel or other suitable metals, acyl substituted cellulose acetates and alkyl derivatives thereof; partially and completely hydrolysed alkylene-vinyl acetate copolymers; unplasticized polyvinyl acetate, cross-linked homo- and copolymers of polyvinyl acetate; cross-linked polyesters of acrylic and methacrylic acid, polyvinylalkyl ethers, polyvinyl fluoride, silicone, polycarbonate, polyurethane, polyamide, polysulphones,

polyimides, polyolefins, polybenzimidazoles; styrene acrylonitrile copolymers, cross-linked poly(ethylene oxide), poly(alkylenes), poly(vinylimidazole), poly(esters), chlorosulphonated polyolefins and ethylene-vinyl ester copolymers such as ethylene-vinyl acetate. A preferred material is silicone.

The present invention is illustrated in further detail by way of the following examples.

#### EXAMPLE 1

Isotonic physiological phosphate buffer (IPPB) having a pH of 7.3 was prepared from sodium hydrogen phosphates (0.1 M phosphates) plus 0.2%  $\text{NaN}_3$ . Using this buffer, solutions of additives were prepared as shown in Table 1. Then 40 mg portions of bovine growth hormone in 50 ml sterile centrifuge tubes were wetted with 100  $\mu\text{l}$  of the solutions. The tubes were stored at 37° C. Following the time at 37° C (see Table 1 for times) each 50 ml tube was typically handled as follows. First, 40 ml of IPPB was added to the tube (defined as start of solubilization time). Using a cup sonicator, the wetted material in the tube was effectively suspended/dissolved. The resulting suspension was subsequently vortexed during a period of standing at room temperature. The respective tube was centrifuged for ca. 5 min. X 1900 g (defined as the end of solubilization time). The resulting supernatant was nearly all removed by pipette and the undissolved residue suspended in 20 ml added water. Following centrifugation and supernatant removal, the residue in the tube was dried at room temperature in a Savant Speed Vac Concentrator to a final chamber pressure of ca.20 Pa (150 mT). The pelleted dry residue was removed from the tube and its weight determined by the difference weight of the tube.

In the tables below, radio receptor assays (RRA) and hypox growth test results are given on several of the formulations. The entry "+" indicates substantially 100% activity relative to native bovine growth (bGH) standard, "-" indicates little or no activity and "<" indicates some intermediate level of activity. Two symbols designate an intermediate result.

In the following examples, the bovine growth hormones identified as Lot 7500(1), Lot 7237C, Lot 8096C and 7500 were Parlow purified pituitary growth hormones which were purchased from A.F. Parlow of the University of California School of Medicine, Harbor General Hospital, Torrance, California.

## EXAMPLE 2

## Control Experiments

A number of control experiments were conducted following the procedure of Example 1. Table 2 below lists the respective data from these control experiments. As can be seen from Table 2 below, IPPB solution alone provides from 39 to 52 weight percent of insolubles. Therefore, any decrease in the amount of insolubles below this range is viewed as an improvement. Many of the candidates in the table below, while  
5 providing a substantial decrease in the formation of insolubles, do not retain the bioactivity to an acceptable level. Surprisingly, many of the polyols which are described in the prior art as being suitable stabilizers for maintaining the fluidity of various proteins are not suitable for use with growth promoting hormones.

## EXAMPLE 3

Two experiments were conducted using Parlow bGH which was dry mixed with a stabilizer to simulate the conditions of an implant. The wetting experiments were conducted as follows. Into a 50 ml tube was

charged dry additive plus dry growth hormone and IPPB. The tubes were then sealed and incubated at 37° C for 19 days. After incubation, the samples were analyzed in the same manner as in Example 1. Table 3 below lists the data from the dry additive experiments. The data in Table 3 indicates that the inductions in insolubles were not clearly different than in Example 1 where the additive was first dissolved in solution.

Thus, the simulated implant experiments demonstrate the effectiveness of the present invention.

TABLE 3

## DRY FORMULATIONS

Formulation	bGH Used	Additive	Wt of bGH	Wt of Additive in Solution	Amount of IPPB (μl)	Days @ 37°C	Insolubles As Wt. % of Starting bGH	RRA	Hypox Rat Growth
1	Lot 7237C	Pentaerythritol	40 mg	47 mg	100	19	27	+	
2	Lot 7237C	L-Serine	40 mg	41 mg	150	19	19	+	

To demonstrate the effectiveness of an implant device containing porcine growth hormone and a stabilizer compared to an implant device containing only porcine growth hormone, the following experiments were conducted. Into each of 20 hollow silicon tubes measuring 2 cm × .7 cm was inserted a teflon circular disc in order that each tube has two equal size compartments. In each compartment of 10 tubes (hereinafter Tubes A) was inserted 20 mg of Parlow (Lot 4556) porcine growth hormone. The tubes were then sealed on each end with a microporous polyethylene disc having a pore size of 70 microns. The remaining 10 tubes (hereinafter Tubes B) were prepared in the same manner except that the Parlow porcine growth hormone was a mixture of lots 4654 and 4673. No significant difference between the growth hormone used in tubes A and tubes B was detected. In addition to the growth hormone, tubes B additionally contained 80 mg of sucrose which was homogeneously mixed with the growth hormone prior to insertion into the tubes.

Each tube was implanted subcutaneously behind the ear of a pig. Thereafter, the presence of growth hormone in each pig was measured by analysis of the blood serum levels. The growth hormone was measured in units of ng/ml.

Table 4 below lists the mean number of ng of porcine growth hormone per ml of blood serum corresponding to the time at which the blood serum sample was taken after implantation.

Figure 1 plots out the data of Table 2. In addition, a line is drawn to depict a minimal desired level of 8 ng/ml of growth hormone.

These experiments demonstrate that the stabilized growth hormone formulations provide for higher concentrations of growth hormone in the serum than growth hormone alone.

**TABLE 4**  
**EFFECT OF DELIVERY SYSTEMS ON LEVELS OF**  
**GROWTH HORMONE IN BLOOD SERUM**

Day	Delivery System	
	A	B
1	2.8	35.8
2	3.4	45.0
3	3.8	23.2
5	5.1	25.4
7	4.6	7.0
9	6.9	9.3
11	4.4	2.4
13	2.7	2.0

The above means were adjusted by covariance with the mean blood growth hormone level on the day prior to implantation and for day 0.

#### Claims

Claims for the following Contracting States : AT, BE, CH, DE, FR, GB, GR, IT, LI, LU, NL, SE

1. A stabilized growth promoting formulation comprising a growth promoting hormone and a stabilizer which decreases formation of insolubles and improves preservation of the soluble bioactivity of said hormone in an aqueous environment, said stabilizer comprising one or more of the following:
  - (a) a polyol selected from non-reducing sugars, sugar alcohols, sugar acids, lactose and pentaerythritol, with the proviso that where the polyol is a sugar alcohol, the formulation does not contain carbohydrate polymer(s);
  - (b) an amino acid selected from glycine, sarcosine, lysine, serine, arginine, betaine, N,N-dimethylglycine, aspartic acid, glutamic acid and salts thereof;
  - (c) a polymer of an amino acid having a charged side group at physiological pH selected from

polylysine, polyaspartic acid, polyarginine, polyhistidine, polyornithine and salts thereof;  
 (d) a choline derivative selected from choline chloride, choline dihydrogen citrate, choline bitartrate, choline bicarbonate, tricholine citrate, choline ascorbate, choline borate, choline gluconate, choline phosphate, di(choline)-sulfate and dicholine mucate.

2. A stabilized growth promoting formulation as claimed in claim 1, wherein said growth promoting hormone is selected from ovine, porcine, equine, avian, human and bovine growth promoting hormones.
3. A stabilized growth promoting formulation as claimed in claim 1 or claim 2, wherein said stabilizer is xylitol.
4. A stabilized growth promoting formulation as claimed in claim 1 or claim 2, wherein said stabilizer is sarcosine.
5. A stabilized growth promoting formulation as claimed in claim 1 or claim 2, wherein said stabilizer is poly DL-lysine HBr.
6. A stabilized growth promoting formulation as claimed in claim 1 or claim 2, wherein said stabilizer is choline chloride.
7. A stabilized growth promoting formulation as claimed in any one of claims 1 to 6, wherein said stabilizer is present at 2.5 to 99 percent by weight of said formulation.
8. A stabilized growth promoting formulation as claimed in any one of claims 1 to 7 which is in a dry state.
9. A stabilized growth promoting formulation as claimed in any one of claims 1 to 7, wherein said formulation is dispersed in an aqueous solution.
10. A stabilized growth promoting formulation as claimed in any one of claims 1 to 7, wherein said formulation is dissolved in an aqueous solution.
11. A method for the stabilization of a growth promoting hormone so as to decrease formation of insolubles and improve preservation of the soluble bioactivity of said hormone in an aqueous environment comprising mixing said hormone with an effective amount of a stabilizer to provide a stabilized growth promoting formulation, said stabilizer comprising one or more of the following:
  - (a) a polyol selected from non-reducing sugars, sugar alcohols, sugar acids, lactose and pentaerythritol, with the proviso that where the polyol is a sugar alcohol, the formulation does not contain carbohydrate polymer(s);
  - (b) an amino acid selected from glycine, sarcosine, lysine, serine, arginine, betaine, N,N-dimethylglycine, aspartic acid, glutamic acid and salts thereof;
  - (c) a polymer of an amino acid having a charged side group at physiological pH selected from polylysine, polyaspartic acid, polyarginine, polyhistidine, polyornithine and salts thereof;
  - (d) a choline derivative selected from choline chloride, choline dihydrogen citrate, choline bitartrate, choline bicarbonate, tricholine citrate, choline ascorbate, choline borate, choline gluconate, choline phosphate, di(choline)-sulfate and dicholine mucate.
12. A method for effecting growth promotion in an animal which comprises administering to the animal an effective amount of a stabilized growth promoting formulation as claimed in any one of claims 1 to 10.

#### Claims for the following Contracting State : ES

1. A method for the stabilization of a growth promoting hormone so as to decrease formation of insolubles and improve perservation of the soluble bioactivity of said hormone in an aqueous environment comprising mixing said hormone with an effective amount of a stabilizer to provide a stabilized growth promoting formulation, said stabilizer comprising one or more of the following:
  - (a) a polyol selected from non-reducing sugars, sugar alcohols, sugar acids, lactose and pentaerythritol, with the proviso that where the polyol is a sugar alcohol, the formulation does not contain carbohydrate polymer(s);

(b) an amino acid selected from glycine, sarcosine, lysine, serine, arginine, betaine, N,N-dimethylglycine, aspartic acid, glutamic acid and salts thereof;

(c) a polymer of an amino acid having a charged side group at physiological pH selected from polylysine, polyaspartic acid, polyarginine, polyhistidine, polyornithine and salts thereof;

(d) a choline derivative selected choline chloride, choline dihydrogen citrate, choline bitartrate, choline bicarbonate, tricholine citrate, choline ascorbate, choline borate, choline gluconate, choline phosphate, di(choline)-sulfate and dicholine mucate.

2. A method as claimed in claim 1, wherein said growth promoting hormone is selected from ovine, porcine, equine, avian, human and bovine growth promoting hormones.

3. A method as claimed in claim 1 or claim 2, wherein said stabilizer is xylitol.

4. A method as claimed in claim 1 or claim 2, wherein said stabilizer is sarcosine

5. A method as claimed in claim 1 or claim 2 wherein said stabilizer is poly DL-lysine HBr.

6. A method as claimed in claim 1 or claim 2, wherein said stabilizer is choline chloride.

7. A method as claimed in any one of claims 1 to 6, wherein said stabilizer is present in said stabilized growth promoting formulation at 2.5 to 99 percent by weight of said formulaion.

8. A method as claimed in any one of claims 1 to 7, wherein said formulation is in a dry state.

9. A method as claimed in any one of claims 1 to 7, wherein said formulation is dispersed in an aqueous solution.

10. A method as claimed in any one of claims 1 to 7, wherein said formulation is dissolved in an aqueous solution.

11. A method for effecting growth promotion in an animal comprising administering to the animal an effective amount of a stabilized growth promoting formulation prepared by a method as claimed in any one of claims 1 to 10.

## Patentansprüche

Patentansprüche für folgende Vertragsstaaten : AT, BE, CH, DE, FR, GB, GR, IT, LI, LU, NL, SE

1. Stabilisierte, wachstumsfördernde Formulierung, umfassend ein wachstumsförderndes Hormon und einen Stabilisator, der die Bildung von unlöslichen Bestandteilen verringert und die Erhaltung der löslichen Bioaktivität des Hormons in einer wäßrigen Umgebung verbessert, wobei der Stabilisator eine oder mehrere der folgenden Verbindungen umfaßt:

(a) ein Polyol, ausgewählt unter nicht-reduzierenden Zuckern, Zuckeralkoholen, Zuckersäuren, Lactose und Pentaerythritol, mit der Maßgabe, daß dann, wenn das Polyol ein Zuckeralkohol ist, die Formulierung kein (keine) Kohlehydratpolymer(e) enthält;

(b) eine Aminosäure, ausgewählt unter Glycin, Sarcosin, Lysin, Serin, Arginin, Betain, N,N-Dimethylglycin, Asparaginsäure, Glutaminsäure und den Salzen davon;

(c) ein Polymer einer Aminosäure mit einer bei physiologischem pH-Wert geladenen Seitengruppe, ausgewählt unter Polylysin, polyasparaginsäure, Polyarginin, Polyhistidin, polyornithin und den Salzen davon; und

(d) ein Cholderivat, ausgewählt unter Cholinchlorid, Cholindihydrogencitrat, Cholinbitartrat, Cholinbicarbonat, Tricholincitrat, Cholinascorbat, Cholinborat, Cholingluconat, Cholinphosphat, Di(cholin)-sulfat und Dicholinmucat.

2. Stabilisierte, wachstumsfördernde Formulierung nach Anspruch 1, worin das wachstumsfördernde Hormon ausgewählt ist unter ovinen, porcinen, equinen, avianen, humanen und bovinen wachstumsfördernden Hormonen.

3. Stabilisierte, wachstumsfördernde Formulierung nach Anspruch 1 oder Anspruch 2, worin der Stabilisa-

tor Xylitol ist.

4. Stabilisierte, wachstumsfördernde Formulierung nach Anspruch 1 oder Anspruch 2, worin der Stabilisator Sarcosin ist.

5. Stabilisierte, wachstumsfördernde Formulierung nach Anspruch 1 oder Anspruch 2, worin der Stabilisator Poly-DL-lysin HBr ist.

6. Stabilisierte, wachstumsfördernde Formulierung nach Anspruch 1 oder Anspruch 2, worin der Stabilisator Cholinchlorid ist.

7. Stabilisierte, wachstumsfördernde Formulierung nach einem der Ansprüche 1 bis 6, worin der Stabilisator in einem Anteil von 2,5 - 99%, bezogen auf das Gewicht der Formulierung, enthalten ist.

8. Stabilisierte, wachstumsfördernde Formulierung nach einem der Ansprüche 1 bis 7 in trockenem Zustand.

9. Stabilisierte, wachstumsfördernde Formulierung nach einem der Ansprüche 1 bis 7, worin die Formulierung in einer wäßrigen Lösung dispergiert ist.

10. Stabilisierte, wachstumsfördernde Formulierung nach einem der Ansprüche 1 bis 7, worin die Formulierung in einer wäßrigen Lösung gelöst ist.

11. Verfahren zur Stabilisierung eines wachstumsfördernden Hormons zur Verringerung der Ausbildung unlöslicher Bestandteile und zur Verbesserung der Erhaltung der löslichen Bioaktivität des Hormons in wäßriger Umgebung, wobei man das Hormon mit einer wirksamen Menge eines Stabilisators vermischt, um eine stabilisierte, wachstumsfördernde Formulierung bereitzustellen, wobei der Stabilisator eine oder mehrere der folgenden Verbindungen umfaßt:

(a) ein Polyol, ausgewählt unter nicht-reduzierenden Zuckern, Zuckeralkoholen, Zuckersäuren, Lactose und Pentaerythritol, mit der Maßgabe, daß dann, wenn das Polyol ein Zuckeralkohol ist, die Formulierung kein (keine) Kohlehydratpolymer(e) enthält;

(b) einer Aminosäure, ausgewählt unter Glycin, Sarcosin, Lysin, Serin, Arginin, Betain, N,N-Dimethylglycin, Asparaginsäure, Glutaminsäure und den Salzen davon;

(c) einem Polymer einer Aminosäure mit einer bei physiologischem pH-Wert geladenen Seitengruppe, ausgewählt unter Polylysin, Polyasparaginsäure, Polyarginin, Polyhistidin, Polyornithin und den Salzen davon; und

(d) einem Cholinderivat, ausgewählt unter Cholinchlorid, Cholin Dihydrogencitrat, Cholinbitartrat, Cholinbicarbonat, Tricholincitrat, Cholinascorbat, Cholinborat, Cholingluconat, Cholinphosphat, Di(cholin)sulfat und Dicholinmucate.

12. Verfahren zur Bewirkung der Wachstumsförderung in einem Tier, wobei man dem Tier eine wirksame Menge einer stabilisierten, wachstumsfördernden Formulierung gemäß einem der Ansprüche 1 bis 10 verabreicht.

#### Patentansprüche für folgenden Vertragsstaat : ES

## Revendications

Revendications pour les Etats contractants suivants : AT, BE, CH, DE, FR, GB, GR, IT, LI, LU, NL, SE

- 35 1. Composition favorisant la croissance, stabilisée, comprenant une hormone favorisant la croissance et un agent de stabilisation qui diminue la formation de substances insolubles et améliore la conservation de la bioactivité soluble de l'hormone en question dans un environnement aqueux, l'agent de stabilisation ou stabilisant précité comprenant un ou plusieurs des composés qui suivent :
  - 40 (a) un polyol choisi parmi des sucres non réducteurs, des sucres-alcools, des sucres-acides, le lactose et le pentaérythritol, avec la condition que lorsque le polyol est un sucre-alcool, la composition ne contient pas de polymère(s) d'hydrates de carbone,
  - (b) un aminoacide choisi parmi la glycine, la sarcosine, la lysine, la sérine, l'arginine, la bétaïne, la N,N-diméthylglycine, l'acide aspartique, l'acide glutamique et leurs sels,
  - 45 (c) un polymère d'un acide aminé possédant un groupe latéral chargé au pH physiologique, choisi parmi la polylysine, l'acide polyaspartique, la polyarginine, la polyhistidine, la polyornithine et leurs sels,
  - (d) un dérivé de choline, choisi parmi le chlorure de choline, le citrate dihydrogéné de choline, le bitartrate de choline, le bicarbonate de choline, le citrate de tricholine, l'ascorbate de choline, le borate de choline, le gluconate de choline, le phosphate de choline, le sulfate de di(choline) et le mucate de dicholine.
  - 50
2. Composition favorisant la croissance, stabilisée, selon la revendication 1, caractérisée en ce que l'hormone favorisant la croissance précitée est choisie parmi les hormones favorisant la croissance
  - 55 ovine, porcine, équine, aviaire, humaine et bovine.
3. Composition favorisant la croissance, stabilisée, suivant la revendication 1 ou la revendication 2, caractérisée en ce que le stabilisant est le xylitol.

4. Composition favorisant la croissance, stabilisée, suivant la revendication 1 ou la revendication 2, caractérisée en ce que le stabilisant est la sarcosine.
5. Composition favorisant la croissance, stabilisée, suivant la revendication 1 ou la revendication 2, caractérisée en ce que le stabilisant est le bromhydrate de poly DL-lysine.
6. Composition favorisant la croissance, stabilisée, suivant la revendication 1 ou la revendication 2, caractérisée en ce que le stabilisant est le chlorure de choline
7. Composition favorisant la croissance, stabilisée, suivant l'une quelconque des revendications 1 à 6, caractérisée en ce que le stabilisant est présent à raison de 2,5 à 99% en poids de la composition.
8. Composition favorisant la croissance, stabilisée, suivant l'une quelconque des revendications 1 à 7, caractérisée en ce qu'elle se trouve à l'état sec.
9. Composition favorisant la croissance, stabilisée, suivant l'une quelconque des revendications 1 à 7, caractérisée en ce qu'elle est dispersée dans une solution aqueuse.
10. Composition favorisant la croissance, stabilisée, suivant l'une quelconque des revendications 1 à 7, caractérisée en ce qu'elle est dissoute dans une solution aqueuse.
11. Procédé de stabilisation d'une hormone favorisant la croissance de manière à diminuer la formation de substances insolubles et à améliorer la conservation de la bioactivité soluble de l'hormone en question dans un environnement aqueux, caractérisé en ce que l'on mélange cette hormone à une proportion efficace d'un stabilisant pour obtenir une composition favorisant la croissance, stabilisée, le stabilisant en question comprenant un ou plusieurs des composés qui suivent :
  - (a) un polyol choisi parmi des sucres non réducteurs, des sucres-alcools, des sucres-acides, le lactose et le pentaérythritol, avec la condition que lorsque le polyol est un sucre-alcool, la composition ne contient pas de polymère(s) d'hydrates de carbone,
  - (b) un aminoacide choisi parmi la glycine, la sarcosine, la lysine, la sérine, l'arginine, la bétaïne, la N,N-diméthylglycine, l'acide aspartique, l'acide glutamique et leurs sels,
  - (c) un polymère d'un acide aminé possédant un groupe latéral chargé au pH physiologique, choisi parmi la polylysine, l'acide polyaspartique, la polyarginine, la polyhistidine, la polyornithine et leurs sels,
  - (d) un dérivé de choline, choisi parmi le chlorure de choline, le citrate dihydrogéné de choline, le bitartrate de choline, le bicarbonate de choline, le citrate de tricholine, l'ascorbate de choline, le borate de choline, le gluconate de choline, le phosphate de choline, le sulfate de di(choline) et le mucate de dicholine.
12. Procédé pour favoriser la croissance d'un animal, caractérisé en ce que l'on administre à cet animal une proportion efficace d'une composition favorisant la croissance, stabilisée, suivant l'une quelconque des revendications 1 à 10.

#### Revendications pour l'Etat contractant suivant : ES

## Description

The present invention provides a stabilized growth hormone, a method for its preparation and a process for effecting growth promotion in an animal by administering an effective amount of stabilized growth promoting hormone. The stabilizers decrease the formation of insolubles and preserve the soluble bioactivity of the growth promoting hormone in aqueous environments. One major problem in the administration of growth promoting hormones is the denaturation of the native globular structure causing aggregation of the growth hormone into precipitated forms which decreases the amount of active growth hormone available. The formation of these insolubles can also block tubing, membranes and various pumps of the implanted delivery devices. System failure almost always results due to the formation of these insolubles. In addition to the formation of insolubles, another problem in the administration of growth promoting hormones is retaining the soluble bioactivity of the hormone. Therefore, to properly serve as a stabilizer for growth promoting formulations, the stabilizer must decrease the formation of insolubles and maintain the bioactivity of the soluble growth hormone.

A variety of stabilizers have been disclosed in the art which avoid the breakdown of the structures of proteins. For example, glycerol has been used to stabilize the activity of various proteins. Gekko, et al., *Biochemistry* (1981), 20, pp. 4666-76. Examples of proteins which are described in this article include chymotrypsinogen A (from bovine pancreas), ribonuclease A (from bovine pancreas),  $\beta$ -lactoglobulin (from milk), bovine serum albumin, insulin (bovine pancreatic), egg-white lysozyme and  $\alpha$ -chymotrypsin.

U.S. Patent No. 4,179,337 discloses a process for coupling a polypeptide such as enzymes and insulin to polyethylene glycol or polypropylene glycol having a molecular weight of 500 to 20,000 daltons. The polyethylene glycol or polypropylene glycol is described as protecting the polypeptide from loss of activity and the composition can be injected without any immunogenic response.

U.S. Patent No. 4,439,181 discloses a method for preventing the precipitation of proteins within drug delivery systems that depend on the fluidity of the infusate for proper function. The method comprises mixing a polyol with the protein solution prior to introduction of the solution into the drug delivery system. Examples of the polyols which are described include glycerol and biocompatible C-4 to C-18 polyols. Exemplary of the polyols are erythritol, arabinose, xylose, ribose, adonitol, arabitol, rhamnose, inositol, fructose, galactose, glucose, mannose, sorbose, maltose, sucrose, melezitose, and raffinose. The solid polyols are dissolved in a standard aqueous solution and admixed with the insulin to provide the final concentration of polyol in the solution of about 10 to 30 percent weight per volume, with the balance being the protein. Other proteins which are described as being subject to the same precipitation problems include growth hormone, glucagon and the like.

EP-A-0193917 describes growth hormone preparations containing large water-soluble carbohydrate polymers which act to delay release of the growth hormone from the preparation. The compositions may also contain a variety of additional constituents, including for example sorbitol, but no mention is made of the potential uses of sorbitol, in the absence of a large carbohydrate polymer, in conjunction with growth hormones and further does not disclose the stabilizing effect of sorbitol on the growth hormone.

While the prior art has taught a number of various stabilizers for specific proteins, unfortunately, the fact a particular stabilizer is effective with a particular protein does not necessarily mean that the particular stabilizer is appropriate for the stabilization of a growth promoting hormone. Therefore, there exists a need for a method of stabilization of a growth promoting hormone which decreases the formation of insolubles and preserves the soluble bioactivity of the hormone.

The present invention concerns a stabilized animal growth promoting hormone and a method for its manufacture. This invention provides for the decreased formation of insolubles and preservation of the soluble bioactivity of the growth promoting hormone in an aqueous environment. The stabilized growth hormone can be formed by mixing a growth promoting hormone with an effective amount of a stabilizer selected from one or more of the following:

- (a) a polymer of an amino acid having a charged side group at a physiological pH selected from polylysine, polyaspartic acid, polyarginine, polyhistidine, polyornithine and salts thereof;
- (b) a choline derivative selected from choline chloride, choline dihydrogen citrate, choline bitartrate, choline bicarbonate, tricholine citrate, choline ascorbate, choline berate, choline gluconate, choline phosphate, di(choline)sulfate and dicholine mucate.

Fig. 1 is a graph showing the mean number of ng of porcine growth hormone per ml of blood serum corresponding to the time at which the blood serum sample was taken after implantation.

The present invention is directed to a stabilized animal growth promoting hormone, a method for its preparation and a process for effecting growth promotion in an animal by administering an effective amount of the stabilized growth promoting hormone. The stabilizers of the present invention not only decrease the formation of insolubles but preserve the bioactivity of the soluble portion of the growth hormone. According to the present invention, an effective amount of a stabilizer is mixed with a growth promoting hormone prior to administration of the hormone to the animal. In one embod-

iment of the present invention, the stabilized growth promoting hormones are injected into the animal. In this embodiment, the stabilized growth hormones are in an aqueous solution comprising dissolved growth hormone and dissolved stabilizer. According to another embodiment of the present invention, the stabilized growth promoting hormones are administered via an implant device. According to this embodiment, the stabilized growth hormones can be in a liquid or dry state. Preferably, when an implant device is elected for the method of administration, the stabilized growth hormone is in the form of a dry mixture comprising solid growth hormone and solid stabilizer which, upon implantation in an aqueous environment, gets wetted and starts to dissolve.

The stabilizers are particularly suited for animal growth promoting hormones. Examples of such hormones include bovine, human, equine, avian, ovine and porcine growth promoting hormones. Preferably, the hormone is bovine or porcine growth promoting hormone. While the concentration of the growth promoting hormone may vary depending on the desired dosage and the particular growth promoting hormone, the hormone is generally present in amounts of from 1 to 97.5 percent by weight of the total weight of the growth promoting formulation. Preferably, the growth promoting hormone is present in amounts of from 5 to 50 percent of the overall weight of the growth promoting formulation. As one skilled in the art can appreciate, the growth hormones may comprise a high weight percent of the overall weight of the growth promoting formulation when the formulation is in the solid state since water and other suitable aqueous solvents are not needed to enable the formulation to be injectable.

The growth hormones for use in the present invention can be derived by extraction and subsequent concentration techniques from the pituitary glands of various animals. Growth hormones which are produced by recombinant DNA methods are also suitable. The amino acid sequences of various hormones which are suitable in the present invention are known. For example, the amino acid sequence of human growth promoting hormones is described in an article by C.H. Li in Kirk-Othmer "Encyclopedia of Chemical Technology", 3rd E., Vol. 12, pp. 549-552. The amino acid sequence of bovine growth hormone is described in an article by R.P. Woychik, Nucleic Acid Res., **10**, 7197 (1982). The amino acid sequence of ovine growth hormone is described in an article by C.H. Liu *et al.*, Arch. Biochem. Biophys., **156**, 493-508 (1973). The amino acid sequence of porcine growth hormone is described in an article by P.H. Seeburg *et al.*, DNA, **2**, 37, 45 (1983). In addition to the above, one can also use growth hormones that have been modified by excision of up to 12 amino acid residues from the amino ends of the amino acid sequences.

The stabilizers which are suitable for the present invention generally have two characteristics. First, they are generally very polar. Second, the stabilizers must be soluble in aqueous solutions. According to one embodiment, the stabilizer is preferably present in amounts sufficient such that when the stabilizer-growth hormone formulation is in an aqueous environment or solution, the solution is saturated with the stabilizer. Obviously, the various stabilizers have their own respective solubilities and may be present in different amounts. When the growth promoting formulation is dispersed or dissolved in an aqueous solution, the stabilizer should be from about 5 percent by weight up to total saturation in the aqueous formulation containing the growth hormone. When the dry formulation is elected, the stabilizer may comprise higher weight percentages of the overall formulation since a major constituent, i.e. the water or aqueous solvent is eliminated. Accordingly, the respective weight percentages of the specific stabilizers listed below are inclusive of both aqueous formulations as well as solid formulations containing the stabilizer and growth promoting hormone.

Certain polymers of amino acids have been found to be useful stabilizers for growth hormones. These polyamino acids or salts thereof can be characterized by charged side groups at physiological pH. The charge can be either "+" or "-". Some examples of polyamino acids which provide a stabilizing effect include polylysine, polyaspartic acid, pol-yarginine, polyhistidine, polyornithine and salts of such polyamino acids. Preferably, the polyamino acid salt is poly DL-lysine HBr. Generally, these particular stabilizers are present in amounts of from 2.5 to 99 percent by weight of the total weight of the overall formulation. Preferably, the polyamino acid derivative is present in amounts of from 15 to 60 percent by weight.

Another class of stabilizers which can be used are derivatives of choline. Examples of such stabilizers include choline chloride, choline dihydrogen citrate, choline bitartrate, choline bicarbonate, tricholine citrate, choline ascorbate, choline borate, choline gluconate, choline phosphate, di(choline) sulfate and dicholine mucate. Preferably, the choline derivative is choline chloride. Generally, these stabilizers are present in amounts of from 2.5 to 99 percent by weight of the total weight of the overall formulation prior to introduction into an aqueous environment. Preferably, the choline derivative is present in amounts of from 15 to 60 percent by weight of the total weight of the overall formulation.

The preparation of the stabilized growth promoting formulations containing the stabilizer and the growth hormone may be by simple mechanical mixing. When an injectable form of the stabilized growth promoting formulation is desired, the stabilizer is first dispersed in an aqueous solution which can be stirred or shaken to bring about a more rapid solubilization of the stabilizer. After the aqueous solution of the stabilizer has been formed, the growth promoting hormone is added. The weight percentage of the aqueous solvent or water need only be an amount sufficient to dissolve the stabilizer and growth hormone and to allow the formulation to be administered by injection. Amounts ranging from 40 to 90 percent by weight are believed to be suitable. While the above procedure has been described as being the preferred, the order of addition can be altered. In another embodiment, the stabilizer and growth hormone can be wet or dry mixed to provide a solid formulation which is particularly suited for implants. After the growth hormone and the stabilizer have

been mixed, any other optional additives, such as buffers, salts and adjuvants, may be added.

Since the present growth hormone formulations are intended to be administered to an animal, the pH must be physiologically acceptable to the animal and not contribute to the destabilization of the growth promoting hormone. Generally, the pH of the stabilized growth promoting formulation ranges from 4 to 10, with the preferred pH range being from 6.5 to 8.0. The pH of the growth promoting formulation can be adjusted by effective amounts of a pharmaceutically acceptable base or acid to obtain the required pH. Suitable acids and bases are known to those skilled in the art.

This invention additionally provides a method for effecting growth promotion in animals which comprises administering to the animal an effective amount of a stabilized growth promoting formulation comprising a growth promoting amount of a growth promoting hormone with a stabilizing amount of a stabilizer selected from one or more of the following:

(a) a polymer of an amino acid having charged side groups at physiological pH selected from polylysine, polyaspartic acid, polyarginine, polyhistidine, polyornithine and salts thereof;

(b) a choline derivative selected from choline chloride, choline dihydrogen citrate, choline bitartrate, choline bicarbonate, tricholine citrate, choline ascorbate, choline borate, choline gluconate, choline phosphate, di(choline)sulfate and dicholine mucate.

The growth promoting formulations are for administration to an animal and preferably pigs and cows. These formulations can be administered in a variety of ways. In one embodiment, the growth promoting formulation can be in a liquid form of solution which is administered by subcutaneous injection or via a liquid containing reservoir of an implanted delivery device.

In another embodiment, the stabilized growth hormone formulation is compressed into tablet or pellet form prior to being placed in a reservoir of a delivery device. In order to formulate pellets from the stabilized growth promoting formulation, various binders are preferably used. Examples of binders which are suitable include sodium bentonite, ethyl cellulose, stearic acid, calcium stearate, adipic acid, fumaric acid, polyethylene glycol, deacetylated chitin and cellulose acetate. Generally, the binder is present in amounts of from .5 to 10 percent by weight of the total weight of the solid growth promoting formulation. Preferably, the binder is present in amounts of from 1 to 5 percent by weight.

Lubricants are preferably added to the pellet to assist in the achievement of a sustained release pattern of the pellet and to assist in the ease of manufacture. Examples of such lubricants includes those common tablet water insoluble lubricants such as, for example, magnesium stearate, sodium stearate, calcium stearate, powdered stearate acid, talc, paraffin, cocoa butter, graphite, lycopodium or combinations thereof. Preferably, the lubricant is a fatty acid derivative such as the stearates, including magnesium stearate, sodium stearate, and calcium stearate. While the amount of lubricant may vary, the lubricant is generally present in amounts of from 0.5 to 10 percent by weight of the total weight of the pellet. Preferably, the lubricant is present in amounts of from 1 to 5 percent by weight.

The stabilized growth hormone formulation, preferably pelletized, may be placed within the reservoir of a delivery device. The reservoir is defined and surrounded by a wall, at least a portion of which comprises a porous membrane. The materials suitable for forming the porous part of the external wall of the device are generally those through which the stabilizer and growth hormone can pass via pores. The pore size of the porous materials can be from 5  $\mu\text{m}$  to 250  $\mu\text{m}$ , with 10 to 100  $\mu\text{m}$  being preferred. Suitable materials for forming these walls are naturally occurring or synthetic materials that are biologically compatible with body fluids, tissues and organs and essentially insoluble in body fluids with which the device will come into contact. The use of materials soluble in body fluids is undesirable, since dissolution of the wall of the device would affect both the rate of release of the growth hormone and the capability of the system to remain in place for prolonged periods of time. The material also desirably is characterized by constant porosity; if the porosity changes over time the rate of release of the growth hormone also will change over time.

Materials suitable for forming the porous portion of the wall of the device are known in the art as having a plurality of fused particles which provide a supporting structure having microscopic sized interconnecting pores. A variety of such materials are commercially available or can be made by different methods known in the art, including etched nuclear track, leaching, polyelectrolytic processes, ion exchange polymer reactions and other techniques. See, for example, Synthetic Polymer Membranes, R.E. Kesting, Chapters 4 and 5, published by McGraw-Hill, 1971; and Chemical Reviews: Ultrafiltration 18: 363-455 (1934).

Microporous materials useful for making these parts of the devices of the present invention include microporous polyalkylenes, such as microporous polyethylene, microporous polycarbonates, microporous polyamides, microporous modacrylic copolymers, polyesters prepared by esterification of a dicarboxylic acid or anhydride with an alkylene polyol, phenolic polyesters, cross-linked olefin polymers, polyolefins, polyurethanes, polyimides, and polybenzimidazoles. Preferred microporous materials are microporous polyethylene.

As one skilled in the art can appreciate, the rate of diffusion of the contents of the reservoir will depend upon the particular material, the ingredients of the reservoir, pore size of the porous material and the dimensions of the porous materials, i.e. thickness and surface area. While the present invention is not limited to any particular dimensions of the

porous portion of the device, excellent results have been achieved with microporous polyethylene discs having a pore size of from 10 to 70  $\mu\text{m}$ , a diameter of 2 to 4 mm and thickness of 1.5 to 3 mm.

In the devices which can be advantageously used in connection with the present invention, typically only a portion of the external wall comprises a porous material. The remainder of the wall comprises a material that is essentially impermeable to the growth hormone and stabilizer(s) contained in the reservoir and to body fluids which are in contact with the implanted or inserted device. This portion of the external wall desirably is characterized much as the porous part of the wall was characterized above. The material should be compatible with body fluids, tissues and organs, and can comprise materials which are commercially available or can be made by processes known in the art. Suitable impermeable materials include steel or other suitable metals, acyl substituted cellulose acetates and alkyl derivatives thereof; partially and completely hydrolysed alkylene-vinyl acetate copolymers; unplasticized polyvinyl acetate, cross-linked homo- and copolymers of polyvinyl acetate; cross-linked polyesters of acrylic and methacrylic acid, polyvinylalkyl ethers, polyvinyl fluoride, silicone, polycarbonate, polyurethane, polyamide, polysulphones, polyimides, polyolefins, polybenzimidazoles; styrene acrylonitrile copolymers cross-linked poly(ethylene oxide), poly(alkylenes), poly(vinylimidazole), poly(esters), chlorosulphonated polyolefins and ethylene-vinyl ester copolymers such as ethylene-vinyl acetate. A preferred material is silicone.

The present invention is illustrated in further detail by way of the following examples.

#### EXAMPLE 1

Isotonic physiological phosphate buffer (IPPB) having a pH of 7.3 was prepared from sodium hydrogen phosphates (0.1 M phosphates) plus 0.2%  $\text{NaN}_3$ . Using this buffer, solutions of additives were prepared as shown in Table 1. Then 40 mg portions of bovine growth hormone in 50 ml sterile centrifuge tubes were wetted with 100  $\mu\text{l}$  of the solutions. The tubes were stored at 37° C. Following the time at 37° C (see Table 1 for times) each 50 ml tube was typically handled as follows. First, 40 ml of IPPB was added to the tube (defined as start of solubilization time). Using a cup sonicator, the wetted material in the tube was effectively suspended/dissolved. The resulting suspension was subsequently vortexed during a period of standing at room temperature. The respective tube was centrifuged for ca. 5 min. X 1900 g (defined as the end of solubilization time). The resulting supernatant was nearly all removed by pipette and the undissolved residue suspended in 20 ml added water. Following centrifugation and supernatant removal, the residue in the tube was dried at room temperature in a Savant Speed Vac Concentrator to a final chamber pressure of ca. 20 Pa (150 mT). The pelleted dry residue was removed from the tube and its weight determined by the difference weight of the tube.

In the tables below, radio receptor assays (RRA) and hypox growth test results are given on several of the formulations. The entry "+" indicates substantially 100% activity relative to native bovine growth (bGH) standard, "-" indicates little or no activity and "<" indicates some intermediate level of activity. Two symbols designate an intermediate result.

In the following examples, the bovine growth hormones identified as Lot 7500(1), Lot 7237C, Lot 8096C and 7500 were Parlow purified pituitary growth hormones which were purchased from A.F. Parlow of the University of California School of Medicine, Harbor General Hospital, Torrance, California.

Formulations 1-26, 28 and 31-37 are given by way of comparison.

EXAMPLE 2Control Experiments

5        A number of control experiments were conducted following the procedure of Example 1. Table 2 below lists the  
respective data from these control experiments. As can be seen from Table 2 below, IPPB solution alone provides from  
39 to 52 weight percent of insolubles. Therefore, any decrease in the amount of insolubles below this range is viewed  
as an improvement. Many of the candidates in the table below, while providing a substantial decrease in the formation  
of insolubles, do not retain the bioactivity to an acceptable level. Surprisingly, many of the polyols which are described  
10 in the prior art as being suitable stabilizers for maintaining the fluidity of various proteins are not suitable for use with  
growth promoting hormones.

COMPARATIVE EXAMPLE 3

Two experiments were conducted using Parlow bGH which was dry mixed with a stabilizer to simulate the conditions of an implant. The wetting experiments were conducted as follows. Into a 50 ml tube was charged dry additive plus dry growth hormone and IPPB. The tubes were then sealed and incubated at 37°C for 19 days. After incubation, the samples were analyzed in the same manner as in Example 1. Table 3 below lists the data from the dry additive experiments. The data in Table 3 indicates that the inductions in insolubles were not clearly different than in Example 1 where the additive was first dissolved in solution. Thus, the simulated implant experiments demonstrate the effectiveness of the present invention.

TABLE 3

## DRY FORMULATIONS

Formulation	bGH Used	Additive	Wt of bGH	Wt of Additive in Solution	Amount of IPFB ( $\mu$ l)	Days @ 37°C	Insolubles As Wt. % of Starting bGH	Hypox Rat Growth
1	Lot 7237C	Pentaerythritol	40 mg	47 mg	100	19	27	+
2	Lot 7237C	L-Serine	40 mg	41 mg	150	19	19	+

## COMPARATIVE EXAMPLE 4

To demonstrate the effectiveness of an implant device containing porcine growth hormone and a stabilizer compared to an implant device containing only porcine growth hormone, the following experiments were conducted. Into

each of 20 hollow silicon tubes measuring 2 cm × .7 cm was inserted a teflon circular disc in order that each tube has two equal size compartments. In each compartment of 10 tubes (hereinafter Tubes A) was inserted 20 mg of Parlow (Lot 4556) porcine growth hormone. The tubes were then sealed on each end with a microporous polyethylene disc having a pore size of 70 microns. The remaining 10 tubes (hereinafter Tubes B) were prepared in the same manner except that the Parlow porcine growth hormone was a mixture of lots 4654 and 4673. No significant difference between the growth hormone used in tubes A and tubes B was detected. In addition to the growth hormone, tubes B additionally contained 80 mg of sucrose which was homogeneously mixed with the growth hormone prior to insertion into the tubes.

Each tube was implanted subcutaneously behind the ear of a pig. Thereafter, the presence of growth hormone in each pig was measured by analysis of the blood serum levels. The growth hormone was measured in units of ng/ml.

Table 4 below lists the mean number of ng of porcine growth hormone per ml of blood serum corresponding to the time at which the blood serum sample was taken after implantation.

Figure 1 plots out the data of Table 2. In addition, a line is drawn to depict a minimal desired level of 8 ng/ml of growth hormone.

These experiments demonstrate that the stabilized growth hormone formulations provide for higher concentrations of growth hormone in the serum than growth hormone alone.

TABLE 4

EFFECT OF DELIVERY SYSTEMS ON LEVELS OF GROWTH HORMONE IN BLOOD SERUM		
Day	Delivery System	
	A	B
1	2.8	35.8
2	3.4	45.0
3	3.8	23.2
5	5.1	25.4
7	4.6	7.0
9	6.9	9.3
11	4.4	2.4
13	2.7	2.0

The above means were adjusted by covariance with the mean blood growth hormone level on the day prior to implantation and for day 0.

## Claims

**Claims for the following Contracting States : DE, GB, FR, IT, NL, SE, CH, LI, BE, AT, LU, GR**

1. A stabilized growth promoting formulation comprising a growth promoting hormone and a stabilizer which decreases formation of insolubles and improves preservation of the soluble bioactivity of said hormone in an aqueous environment, said stabilizer comprising one or more of the following:

- (a) a polymer of an amino acid having a charged side group at physiological pH selected from the group consisting of polylysine, polyaspartic acid, polyarginine, polyhistidine, polyornithine and salts thereof;
- (b) a choline derivative selected from the group consisting of choline chloride, choline dihydrogen citrate, choline bitartrate, choline bicarbonate, tricholine citrate, choline ascorbate, choline borate, choline gluconate, choline phosphate, di(choline)- sulfate and dicholine mucate.

2. A stabilized growth promoting formulation as claimed in claim 1, wherein said growth promoting hormone is selected from the group consisting of ovine, porcine, equine, avian, human and bovine growth promoting hormones.

3. A stabilized growth promoting formulation as claimed in claim 1 or claim 2, wherein said stabilizer is poly DL-lysine

HBr.

4. A stabilized growth promoting formulation as claimed in claim 1 or claim 2, wherein said stabilizer is choline chloride.
5. A stabilized growth promoting formulation as claimed in any one of claims 1 to 4, wherein said stabilizer is present at 2.5 to 99 percent by weight of said formulation.
6. A stabilized growth promoting formulation as claimed in any one of claims 1 to 5 which is in a dry state.
7. A stabilized growth promoting formulation as claimed in any one of claims 1 to 5, wherein said formulation is dispersed in an aqueous solution.
8. A stabilized growth promoting formulation as claimed in any one of claims 1 to 5, wherein said formulation is dissolved in an aqueous solution.
9. A method for the stabilization of a growth promoting hormone so as to decrease formation of insolubles and improve preservation of the soluble bioactivity of said hormone in an aqueous environment comprising mixing said hormone with an effective amount of a stabilizer to provide a stabilized growth promoting formulation, said stabilizer comprising one or more of the following:
  - (a) a polymer of an amino acid having a charged side group at physiological pH selected from the group consisting of polylysine, polyaspartic acid, polyarginine, polyhistidine, polyornithine and salts thereof;
  - (b) a choline derivative selected from the group consisting of choline chloride, choline dihydrogen citrate, choline bitartrate, choline bicarbonate, tricholine citrate, choline ascorbate, choline borate, choline gluconate, choline phosphate, di(choline)-sulfate and dicholine mucate.
10. A method for effecting growth promotion in an animal which comprises administering to the animal an effective amount of a stabilized growth promoting formulation as claimed in any one of claims 1 to 8.

#### Claims for the following Contracting State : ES

1. A method for the stabilization of a growth promoting hormone so as to decrease formation of insolubles and improve preservation of the soluble bioactivity of said hormone in an aqueous environment comprising mixing said hormone with an effective amount of a stabilizer to provide a stabilized growth promoting formulation, said stabilizer comprising one or more of the following:
  - (a) a polymer of an amino acid having a charged side group at physiological pH selected from the group consisting of polylysine, polyaspartic acid, polyarginine, polyhistidine, polyornithine and salts thereof;
  - (b) a choline derivative selected from the group consisting of choline chloride, choline dihydrogen citrate, choline bitartrate, choline bicarbonate, tricholine citrate, choline ascorbate, choline borate, choline gluconate, choline phosphate, di(choline)-sulfate and dicholine mucate.
2. A method as claimed in claim 1, wherein said growth promoting hormone is selected from the group consisting of ovine, porcine, equine, avian, human and bovine growth promoting hormones.
3. A method as claimed in claim 1 or claim 2 wherein said stabilizer is poly DL-lysine HBr.
4. A method as claimed in claim 1 or claim 2, wherein said stabilizer is choline chloride.
5. A method as claimed in any one of claims 1 to 4, wherein said stabilizer is present in said stabilized growth promoting formulation at about 2.5 to 99 percent by weight of said formulaion.
6. A method as claimed in any one of claims 1 to 5, wherein said formulation is in a dry state.
7. A method as claimed in any one of claims 1 to 5, wherein said formulation is dispersed in an aqueous solution.
8. A method as claimed in any one of claims 1 to 5, wherein said formulation is dissolved in an aqueous solution.

9. A method for effecting growth promotion in an animal comprising administering to the animal an effective amount of a stabilized growth promoting formulation prepared by a method as claimed in any one of claims 1 to 8.

## Patentansprüche

Patentansprüche für folgende Vertragsstaaten : DE, GB, FR, IT, NL, SE, CH, LI, BE, AT, LU, GR

1. Stabilisierte, wachstumsfördernde Formulierung, umfassend ein wachstumsförderndes Hormon und einen Stabilisator, der die Bildung von unlöslichen Bestandteilen verringert und die Erhaltung der löslichen Bioaktivität des Hormons in einer wäßrigen Umgebung verbessert, wobei der Stabilisator eine oder mehrere der folgenden Verbindungen umfaßt:

- a) ein Polymer einer Aminosäure mit einer bei physiologischem pH-Wert geladenen Seitengruppe, ausgewählt unter Polylysin, Polyasparaginsäure, Polyarginin, Polyhistidin, Polyornithin und Salzen davon;  
b) ein Cholderivat, ausgewählt unter Cholinchlorid, Cholindihydrogencitrat, Cholinbitartrat, Cholinbicarbonat, Tricholincitrat, Cholinascorbat, Cholinborat, Cholingluconat, Cholinphosphat, Di(cholin)-sulfat und Dicholinmuc.

2. Stabilisierte, wachstumsfördernde Formulierung nach Anspruch 1, worin das wachstumsfördernde Hormon ausgewählt ist unter ovinen, porcinen, equinen, avianen, humanen und bovinen wachstumsfördernden Hormonen.

3. Stabilisierte, wachstumsfördernde Formulierung nach Anspruch 1 oder Anspruch 2, worin der Stabilisator Poly-DL-lysin HBr ist.

4. Stabilisierte, wachstumsfördernde Formulierung nach Anspruch 1 oder Anspruch 2, worin der Stabilisator Cholinchlorid ist.

5. Stabilisierte, wachstumsfördernde Formulierung nach einem der Ansprüche 1 bis 4, worin der Stabilisator 2,5 - 99 Gewichtsprozent der Formulierung ausmacht.

6. Stabilisierte, wachstumsfördernde Formulierung nach einem der Ansprüche 1 bis 5 in trockenem Zustand.

7. Stabilisierte, wachstumsfördernde Formulierung nach einem der Ansprüche 1 bis 5, worin die Formulierung in einer wäßrigen Lösung dispergiert ist.

8. Stabilisierte, wachstumsfördernde Formulierung nach einem der Ansprüche 1 bis 5, worin die Formulierung in einer wäßrigen Lösung gelöst ist.

9. Verfahren zur Stabilisierung eines wachstumsfördernden Hormons zur Verringerung der Ausbildung unlöslicher Bestandteile und zur Verbesserung der Erhaltung der löslichen Bioaktivität des Hormons in wäßriger Umgebung, wobei man das Hormon mit einer wirksamen Menge eines Stabilisators vermischt, um eine stabilisierte, wachstumsfördernde Formulierung bereitzustellen, wobei der Stabilisator eine oder mehrere der folgenden Verbindungen umfaßt:

- a) ein Polymer einer Aminosäure mit einer bei physiologischem pH-Wert geladenen Seitengruppe, ausgewählt unter Polylysin, Polyasparaginsäure, Polyarginin, Polyhistidin, Polyornithin und Salzen davon;  
b) ein Cholderivat, ausgewählt unter Cholinchlorid, Cholindihydrogencitrat, Cholinbitartrat, Cholinbicarbonat, Tricholincitrat, Cholinascorbat, Cholinborat, Cholingluconat, Cholinphosphat, Di(cholin)-sulfat und Dicholinmuc.

10. Verfahren zum Bewirken von Wachstumsförderung bei einem Tier, wobei man dem Tier eine wirksame Menge einer stabilisierten, wachstumsfördernden Formulierung gemäß einem der Ansprüche 1 bis 8 verabreicht.

Patentansprüche für folgenden Vertragsstaat : ES

1. Verfahren zur Stabilisierung eines wachstumsfördernden Hormons zur Verringerung der Ausbildung unlöslicher Bestandteile und zur Verbesserung der Erhaltung der löslichen Bioaktivität des Hormons in wäßriger Umgebung, wobei man das Hormon mit einer wirksamen Menge eines Stabilisators vermischt, um eine stabilisierte wach-

tumstfördernde Formulierung bereitzustellen, wobei der Stabilisator eine oder mehrere der folgenden Verbindungen umfaßt:

- 5 (a) ein Polymer einer Aminosäure mit einer bei physiologischem pH-Wert geladenen Seitengruppe, ausgewählt unter Polylysin, Polyasparaginsäure, Polyarginin, Polyhistidin, Polyornithin und Salzen davon;  
(b) ein Cholinderivat, ausgewählt unter Cholinchlorid, Cholindihydrogencitrat, Cholinbitartrat, Cholinbicarbonat, Tricholincitrat, Cholinascorbat, Cholinborat, Cholingluconat, Cholinphosphat, Di(cholin)-sulfat und Dicholinmucate.
- 10 2. Verfahren nach Anspruch 1, wobei das wachstumsfördernde Hormon ausgewählt ist unter ovinen, porcinen, equinen, avianen, humanen und bovinen wachstumsfördernden Hormonen.
3. Verfahren nach Anspruch 1 oder Anspruch 2, worin der Stabilisator Poly-DL-lysin HBr ist.
- 15 4. Verfahren nach Anspruch 1 oder Anspruch 2, worin der Stabilisator Cholinchlorid ist.
5. Verfahren nach einem der Ansprüche 1 bis 4, worin der Stabilisator in der stabilisierten wachstumsfördernden Formulierung 2,5 - 99 Gewichtsprozent der Formulierung ausmacht.
- 20 6. Verfahren nach einem der Ansprüche 1 bis 5, worin die Formulierung in trockenem Zustand ist.
7. Verfahren nach einem der Ansprüche 1 bis 5, worin die Formulierung in einer wäßrigen Lösung dispergiert ist.
8. Verfahren nach einem der Ansprüche 1 bis 5, worin die Formulierung in einer wäßrigen Lösung gelöst ist.
- 25 9. Verfahren zum Bewirken von Wachstumsförderung bei einem Tier, wobei man dem Tier eine wirksame Menge einer stabilisierten wachstumsfördernden Formulierung verabreicht, hergestellt gemäß einem Verfahren nach einem der Ansprüche 1 bis 8.

## 30 Revendications

**Revendications pour les Etats contractants suivants : DE, GB, FR, IT, NL, SE, CH, LI, BE, AT, LU, GR**

- 35 1. Composition favorisant la croissance, stabilisée, comprenant une hormone favorisant la croissance et un agent de stabilisation qui diminue la formation de substances insolubles et améliore la conservation de la bioactivité soluble de l'hormone en question dans un environnement aqueux, l'agent de stabilisation ou stabilisant précité comprenant un ou plusieurs des composés qui suivent :  
40 (a) un polymère d'un acide aminé possédant un groupe latéral chargé au pH physiologique, choisi parmi la polylysine, l'acide polyaspartique, la polyarginine, la polyhistidine, la polyornithine et leur sels,  
(b) un dérivé de choline, choisi parmi le chlorure de choline, le citrate dihydrogéné de choline, le bitartrate de choline, le bicarbonate de choline, le citrate de tricholine, l'ascorbate de choline, le borate de choline, le gluconate de choline, le phosphate de choline, le sulfate de di(choline) et le mucate de dicholine.
- 45 2. Composition favorisant la croissance, stabilisée, selon la revendication 1, caractérisée en ce que l'hormone favorisant la croissance précitée est choisie parmi les hormones favorisant la croissance ovine, porcine, équine, aviaire, humaine et bovine.
3. Composition favorisant la croissance, stabilisée suivant la revendication 1 ou la revendication 2, caractérisée en ce  
50 que le stabilisant est le bromhydrate de poly-DL-lysine.
4. Composition favorisant la croissance, stabilisée, suivant la revendication 1 ou la revendication 2, caractérisée en ce que le stabilisant est le chlorure de choline.
- 55 5. Composition favorisant la croissance, stabilisée, suivant l'une quelconque des revendications 1 à 4, caractérisée en ce que le stabilisant est présent à raison de 2,5 à 99% en poids de la composition.
6. Composition favorisant la croissance, stabilisée, suivant l'une quelconque des revendications 1 à 5, caractérisée

en ce qu'elle se trouve à l'état sec.

7. Composition favorisant la croissance, stabilisée, suivant l'une quelconque des revendications 1 à 5, caractérisée en ce qu'elle est dispersée dans une solution aqueuse.

8. Composition favorisant la croissance, stabilisée, suivant l'une quelconque des revendications 1 à 5, caractérisée en ce qu'elle est dissoute dans une solution aqueuse.

9. Procédé de stabilisation d'une hormone favorisant la croissance de manière à diminuer la formation de substances insolubles et à améliorer la conservation de la bioactivité soluble de l'hormone en question dans un environnement aqueux, caractérisé en ce que l'on mélange cette hormone à une proportion efficace d'un stabilisant pour obtenir une composition favorisant la croissance, stabilisée, le stabilisant en question comprenant un ou plusieurs des composés qui suivent :

(a) un polymère d'un acide aminé possédant un groupe latéral chargé au pH physiologique, choisi parmi la polylysine, l'acide polyaspartique, la polyarginine, la polyhistidine, la polyornithine et leur sels,

(b) un dérivé de choline, choisi parmi le chlorure de choline, le citrate dihydrogéné de choline, le bitartrate de choline, le bicarbonate de choline, le citrate de tricholine, l'ascorbate de choline, le borate de choline, le gluconate de choline, le phosphate de choline, le sulfate de di(choline) et le mucate de dicholine.

10. Procédé pour favoriser la croissance d'un animal, caractérisé en ce que l'on administre à cet animal une proportion efficace d'une composition favorisant la croissance, stabilisée, suivant l'une quelconque des revendications 1 à 8.

#### Revendications pour l'Etat contractant suivant : ES

1. Procédé de stabilisation d'une hormone favorisant la croissance de manière à diminuer la formation de substances insolubles et à améliorer la conservation de la bioactivité soluble de l'hormone en question dans un environnement aqueux, caractérisé en ce que l'on mélange cette hormone à une proportion efficace d'un stabilisant pour obtenir une composition favorisant la croissance, stabilisée, le stabilisant en question comprenant un ou plusieurs des composés qui suivent :

(a) un polymère d'un acide aminé possédant un groupe latéral chargé au pH physiologique, choisi parmi la polylysine, l'acide polyaspartique, la polyarginine, la polyhistidine, la polyornithine et leur sels,

(b) un dérivé de choline, choisi parmi le chlorure de choline, le citrate dihydrogéné de choline, le bitartrate de choline, le bicarbonate de choline, le citrate de tricholine, l'ascorbate de choline, le borate de choline, le gluconate de choline, le phosphate de choline, le sulfate de di(choline) et le mucate de dicholine.

2. Procédé suivant la revendication 1, caractérisé en ce que l'hormone favorisant la croissance précitée est choisie parmi les hormones favorisant la croissance ovine, porcine, équine, aviaire, humaine et bovine.

3. Procédé suivant la revendication 1 ou la revendication 2, caractérisé en ce que le stabilisant est le bromhydrate de poly-DL-lysine.

4. Procédé suivant la revendication 1 ou la revendication 2, caractérisé en ce que le stabilisant est le chlorure de choline.

5. Procédé suivant l'une quelconque des revendications 1 à 4, caractérisé en ce que le stabilisant est présent à raison de 2,5 à 99% en poids de la composition.

6. Procédé suivant l'une quelconque des revendications 1 à 5, caractérisé en ce qu'elle se trouve à l'état sec.

7. Procédé suivant l'une quelconque des revendications 1 à 5, caractérisé en ce qu'elle est dispersée dans une solution aqueuse.

8. Procédé suivant l'une quelconque des revendications 1 à 5, caractérisé en ce qu'elle est dissoute dans une solution aqueuse.

9. Procédé pour favoriser la croissance d'un animal, caractérisé en ce que l'on administre à cet animal une proportion

## EP 0 303 746 B2

efficace d'une composition favorisant la croissance, stabilisée, suivant l'une quelconque des revendications 1 à 8.
